 - Principles of SDN

- Link Layer
 - Introduction
 - Error detection

Chapter 6 The Link Layer and LANs

Instructor: Zhuozhao Li

Lab: Qing Wang

Department of Computer Science and Engineering

Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANs
- data center networking

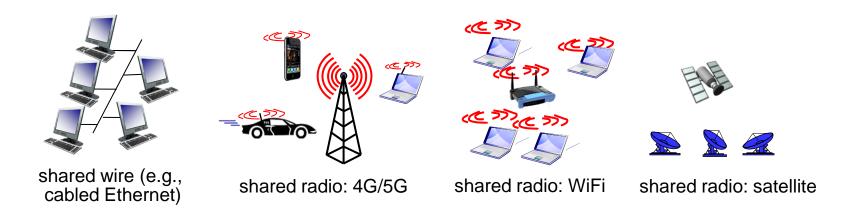

a day in the life of a web request

Multiple access links, protocols

two types of "links":

- point-to-point
 - point-to-point link between Ethernet switch, host
 - PPP for dial-up access
- broadcast (shared wire or medium)
 - old-fashioned Ethernet
 - upstream HFC in cable-based access network
 - 802.11 wireless LAN, 4G/4G. satellite

Multiple access protocols

- single shared broadcast channel
- two or more simultaneous transmissions by nodes: interference
 - collision if node receives two or more signals at the same time

multiple access protocol

- distributed algorithm that determines how nodes share channel,
 i.e., determine when node can transmit
- communication about channel sharing must use channel itself!
 - no out-of-band channel for coordination

An ideal multiple access protocol

given: multiple access channel (MAC) of rate R bps desiderata:

- 1. when one node wants to transmit, it can send at rate R.
- 2. when M nodes want to transmit, each can send at average rate R/M
- 3. fully decentralized:
 - no special node to coordinate transmissions
 - no synchronization of clocks, slots
- 4. simple

MAC protocols: taxonomy

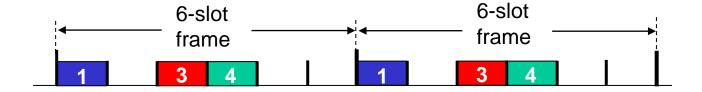

three broad classes:

- channel partitioning
 - divide channel into smaller "pieces" (time slots, frequency, code)
 - allocate piece to node for exclusive use
- random access
 - channel not divided, allow collisions
 - "recover" from collisions
- "taking turns"
 - nodes take turns, but nodes with more to send can take longer turns

Channel partitioning MAC protocols: TDMA

TDMA: time division multiple access

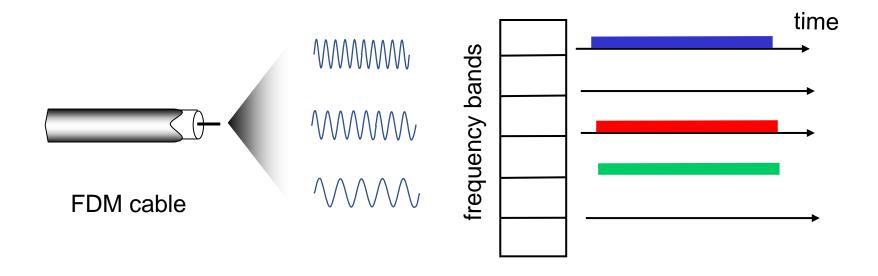

- access to channel in "rounds"
- each station gets fixed length slot (length = packet transmission time) in each round
- unused slots go idle
- example: 6-station LAN, 1,3,4 have packets to send, slots 2,5,6 idle

Channel partitioning MAC protocols: FDMA

FDMA: frequency division multiple access

- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: 6-station LAN, 1,3,4 have packet to send, frequency bands 2,5,6 idle

Random access protocols

- when node has packet to send
 - transmit at full channel data rate R.
 - no a priori coordination among nodes
- two or more transmitting nodes: "collision"
- random access MAC protocol specifies:
 - how to detect collisions
 - how to recover from collisions (e.g., via delayed retransmissions)
- examples of random access MAC protocols:
 - ALOHA, slotted ALOHA
 - CSMA, CSMA/CD, CSMA/CA

Slotted ALOHA

assumptions:

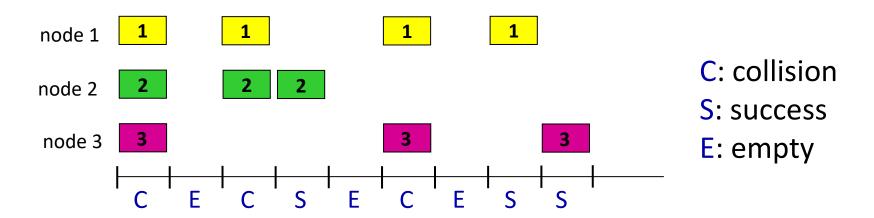

- all frames same size
- time divided into equal size slots (time to transmit 1 frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

operation:

- when node obtains fresh frame, transmits in next slot
 - if no collision: node can send new frame in next slot
 - *if collision:* node retransmits frame in each subsequent slot with probability *p* until success

randomization – why?

Slotted ALOHA

Pros:

- single active node can continuously transmit at full rate of channel
- highly decentralized: only slots in nodes need to be in sync
- simple

Cons:

- collisions, wasting slots
- idle slots
- clock synchronization

Slotted ALOHA: efficiency

efficiency: long-run fraction of successful slots (many nodes, all with many frames to send)

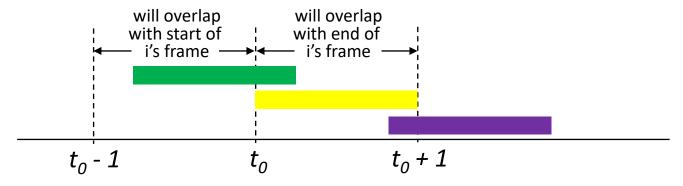

- suppose: N nodes with many frames to send, each transmits in slot with probability p
 - prob that given node has success in a slot = $p(1-p)^{N-1}$
 - prob that any node has a success = $Np(1-p)^{N-1}$
 - max efficiency: find p^* that maximizes $Np(1-p)^{N-1}$
 - for many nodes, take limit of $Np^*(1-p^*)^{N-1}$ as N goes to infinity, gives:

$$max\ efficiency = 1/e = .37$$

at best: channel used for useful transmissions 37% of time!

Pure ALOHA

- unslotted Aloha: simpler, no synchronization
 - when frame first arrives: transmit immediately
- collision probability increases with no synchronization:
 - frame sent at t₀ collides with other frames sent in [t₀-1,t₀+1]

pure Aloha efficiency: 18%!

CSMA (carrier sense multiple access)

simple CSMA: listen before transmit:

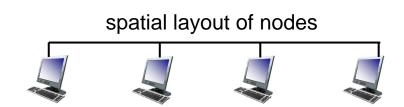

- if channel sensed idle: transmit entire frame
- if channel sensed busy: defer transmission
- human analogy: don't interrupt others!

CSMA/CD: CSMA with collision detection

- collisions detected within short time
- colliding transmissions aborted, reducing channel wastage
- collision detection easy in wired, difficult with wireless
- human analogy: the polite conversationalist

CSMA: collisions

- collisions can still occur with carrier sensing:
 - propagation delay means two nodes may not hear each other's juststarted transmission
- collision: entire packet transmission time wasted
 - distance & propagation delay play role in in determining collision probability

 $\mathsf{t}_1^{}$

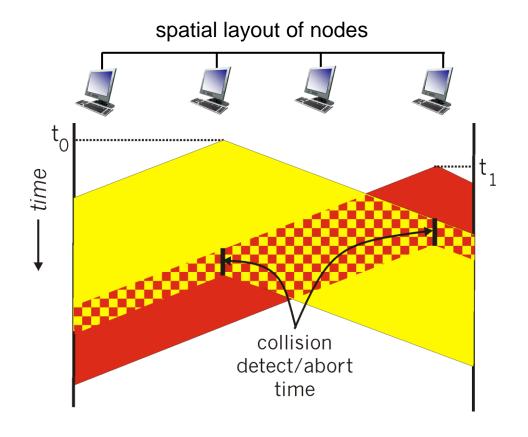

CSMA: collisions

- collisions can still occur with carrier sensing:
 - propagation delay means two nodes may not hear each other's juststarted transmission
- collision: entire packet transmission time wasted
 - distance & propagation delay play role in in determining collision probability

CSMA/CD:

- CSMA/CS reduces the amount of time wasted in collisions
 - transmission aborted on collision detection

Ethernet CSMA/CD algorithm

- 1. NIC receives datagram from network layer, creates frame
- 2. If NIC senses channel:

if idle: start frame transmission.

if busy: wait until channel idle, then transmit

- 3. If NIC transmits entire frame without collision, NIC is done with frame!
- 4. If NIC detects another transmission while sending: abort, send jam signal
- 5. After aborting, NIC enters binary (exponential) backoff:
 - after mth collision, NIC chooses K at random from $\{0,1,2,...,2^m-1\}$. NIC waits K:512 bit times, returns to Step 2
 - more collisions: longer backoff interval

CSMA/CD efficiency

- T_{prop} = max prop delay between 2 nodes in LAN
- t_{trans} = time to transmit max-size frame

$$efficiency = \frac{1}{1 + 5t_{prop}/t_{trans}}$$

- efficiency goes to 1
 - as t_{prop} goes to 0
 - as t_{trans} goes to infinity
- better performance than ALOHA: and simple, cheap, decentralized!

"Taking turns" MAC protocols

channel partitioning MAC protocols:

- share channel efficiently and fairly at high load
- inefficient at low load: delay in channel access, 1/N bandwidth allocated even if only 1 active node!

random access MAC protocols

- efficient at low load: single node can fully utilize channel
- high load: collision overhead

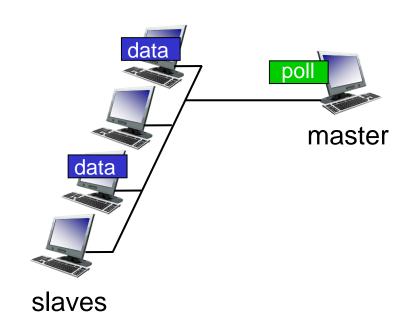

"taking turns" protocols

look for best of both worlds!

"Taking turns" MAC protocols

polling:

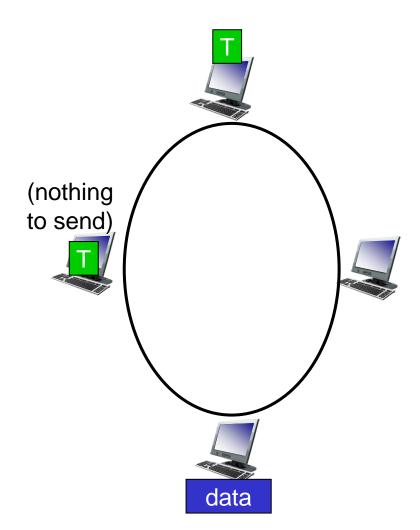

- master node "invites" other nodes to transmit in turn
- typically used with "dumb" devices
- concerns:
 - polling overhead
 - latency
 - single point of failure (master)
- Bluetooth uses polling

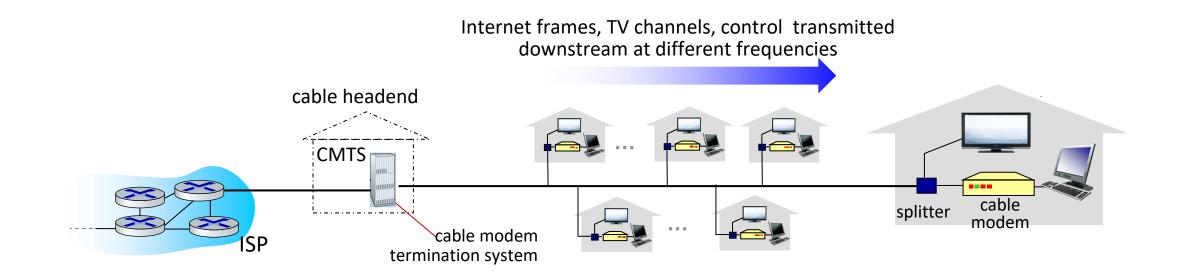

"Taking turns" MAC protocols

token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
 - token overhead
 - latency
 - single point of failure (token)

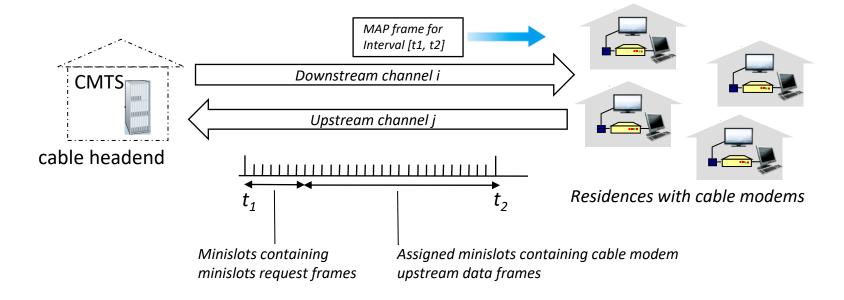

Cable access network: FDM, TDM and random access!

- DOCSIS: data over cable service interface specification
- multiple downstream (broadcast) FDM channels: up to 1.6 Gbps/channel
 - single CMTS transmits into channels
- multiple upstream channels (up to 1 Gbps/channel)
 - multiple access: all users contend (random access) for certain upstream channel time slots; others assigned TDM
 Link Layer: 6-25

Cable access network:

DOCSIS: data over cable service interface specification

- FDM over upstream, downstream frequency channels
- TDM upstream: some slots assigned, some have contention
 - downstream MAP frame: assigns upstream slots
 - request for upstream slots (and data) transmitted random access (binary backoff) in selected slots

Summary of MAC protocols

- channel partitioning, by time, frequency or code
 - Time Division, Frequency Division
- random access (dynamic),
 - ALOHA, S-ALOHA, CSMA, CSMA/CD
 - carrier sensing: easy in some technologies (wire), hard in others (wireless)
 - CSMA/CD used in Ethernet
 - CSMA/CA used in 802.11
- taking turns
 - polling from central site, token passing
 - Bluetooth, FDDI, token ring

Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANs
- data center networking

a day in the life of a web request

MAC addresses

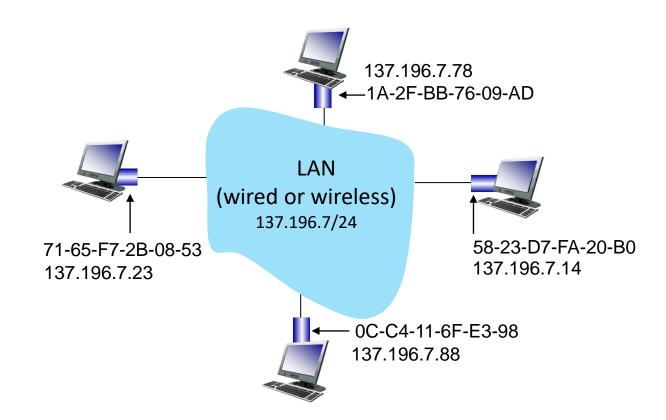

- 32-bit IP address:
 - network-layer address for interface
 - used for layer 3 (network layer) forwarding
 - e.g.: 128.119.40.136
- MAC (or LAN or physical or Ethernet) address:
 - function: used "locally" to get frame from one interface to another physically-connected interface (same subnet, in IP-addressing sense)
 - 48-bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable
 - e.g.: 1A-2F-BB-76-09-AD

hexadecimal (base 16) notation (each "numeral" represents 4 bits)

MAC addresses

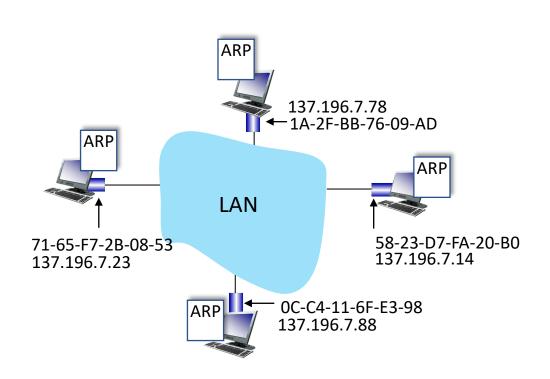

each interface on LAN

- has unique 48-bit MAC address
- has a locally unique 32-bit IP address (as we've seen)

ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

 IP/MAC address mappings for some LAN nodes:

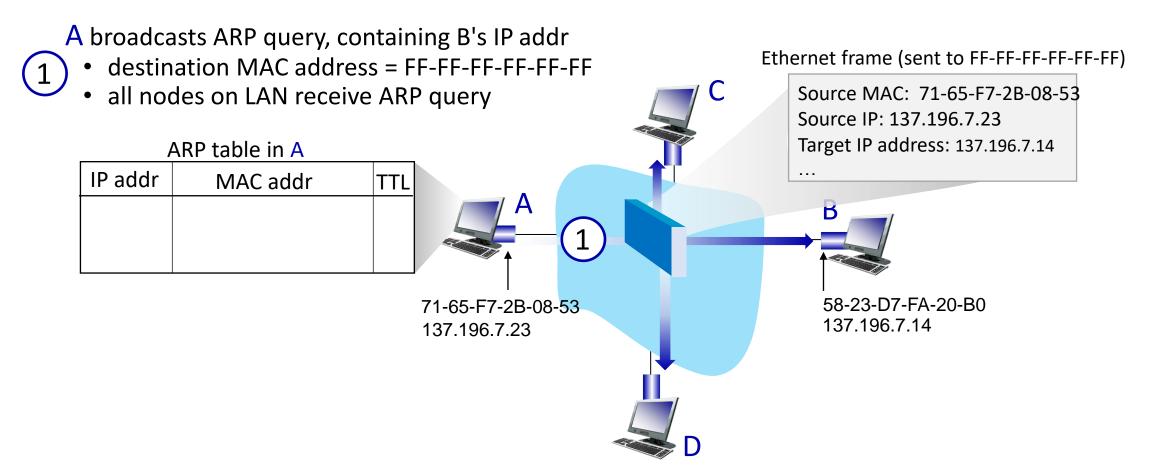

< IP address; MAC address; TTL>

 TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

ARP protocol in action

example: A wants to send datagram to B

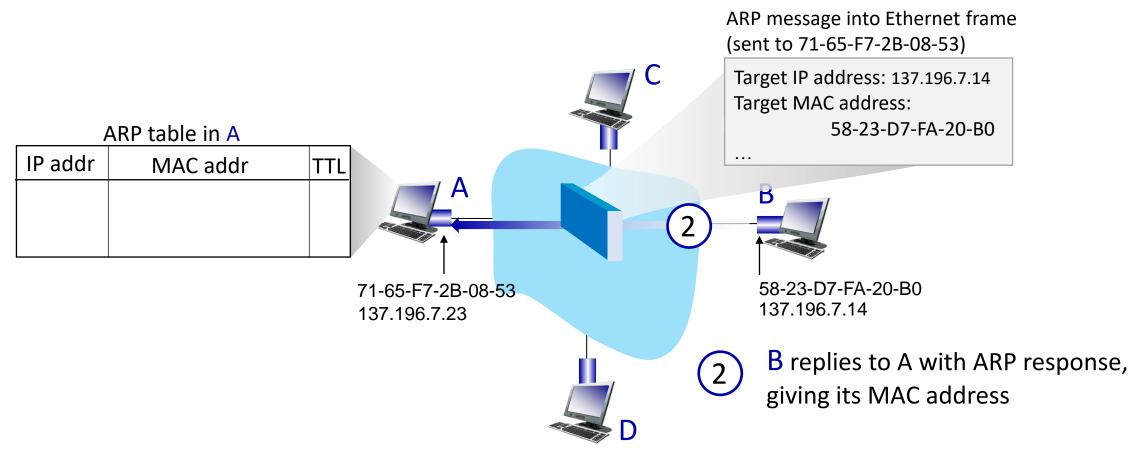

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

ARP protocol in action

example: A wants to send datagram to B

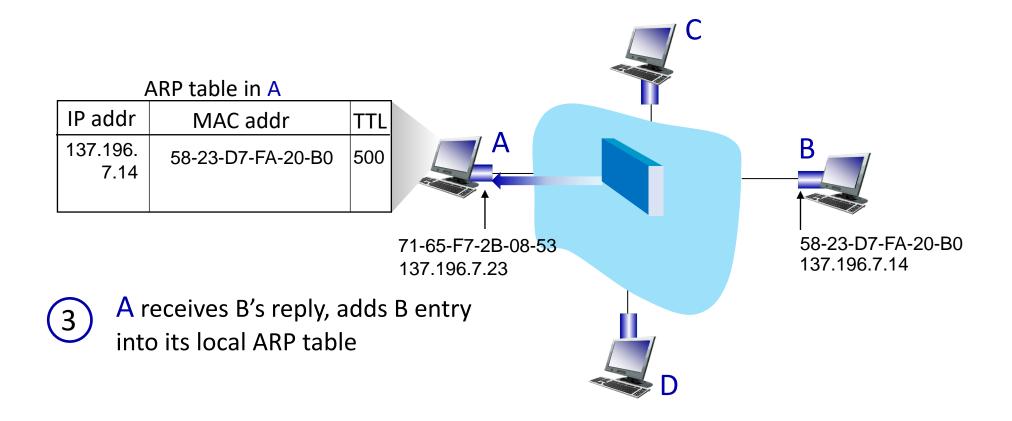

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

ARP protocol in action

example: A wants to send datagram to B

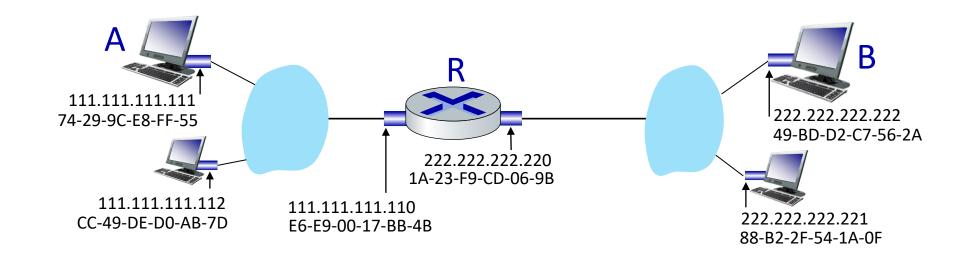

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

Routing to another subnet: addressing

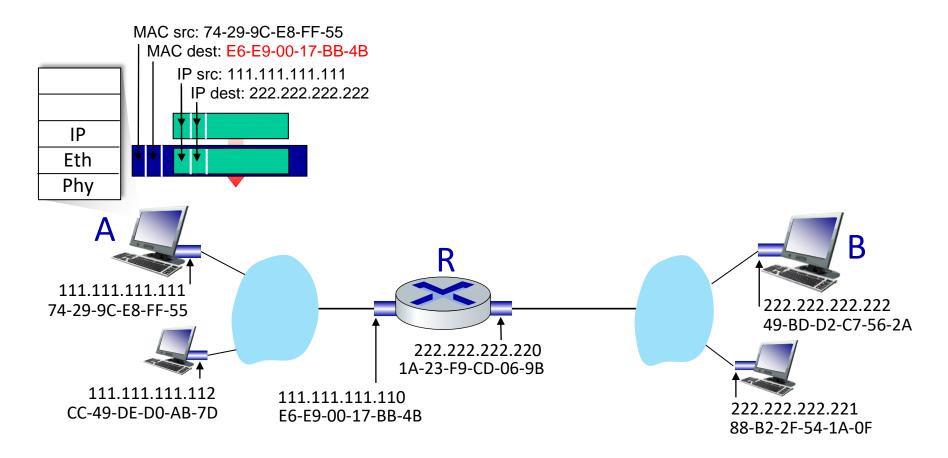

walkthrough: sending a datagram from A to B via R

- focus on addressing at IP (datagram) and MAC layer (frame) levels
- assume that:
 - A knows B's IP address (how?)
 - A knows IP address of first hop router, R (how?)
 - A knows R's MAC address (how?)

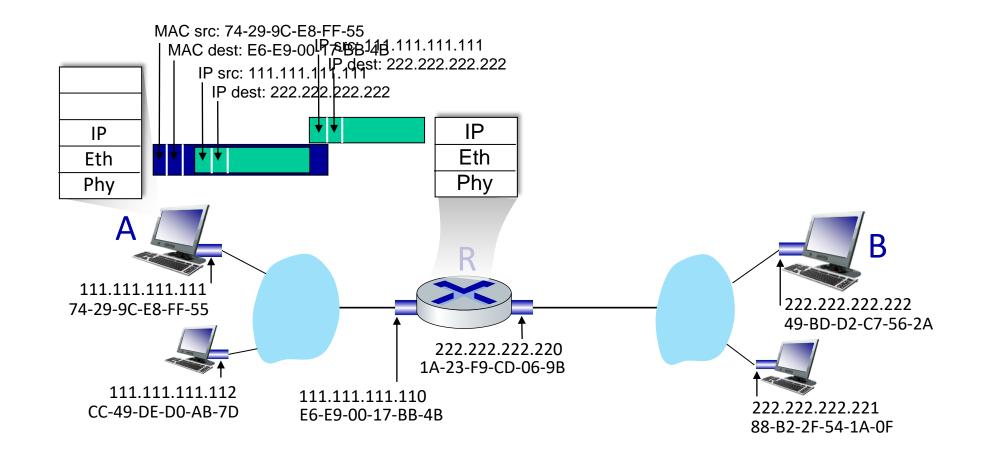

Routing to another subnet: addressing

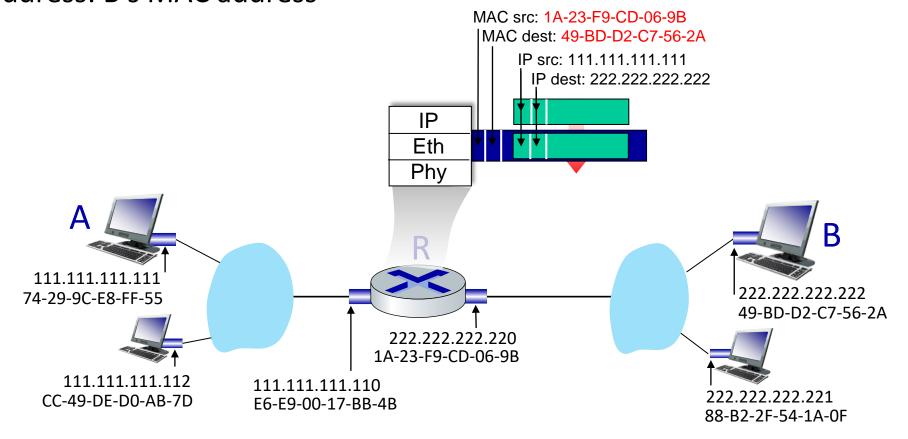

- A creates IP datagram with IP source A, destination B
- A creates link-layer frame containing A-to-B IP datagram
 - R's MAC address is frame's destination

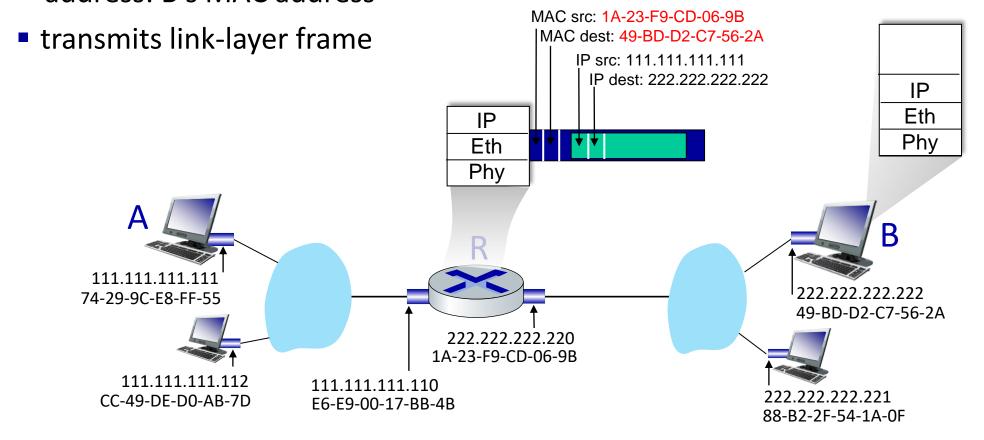

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

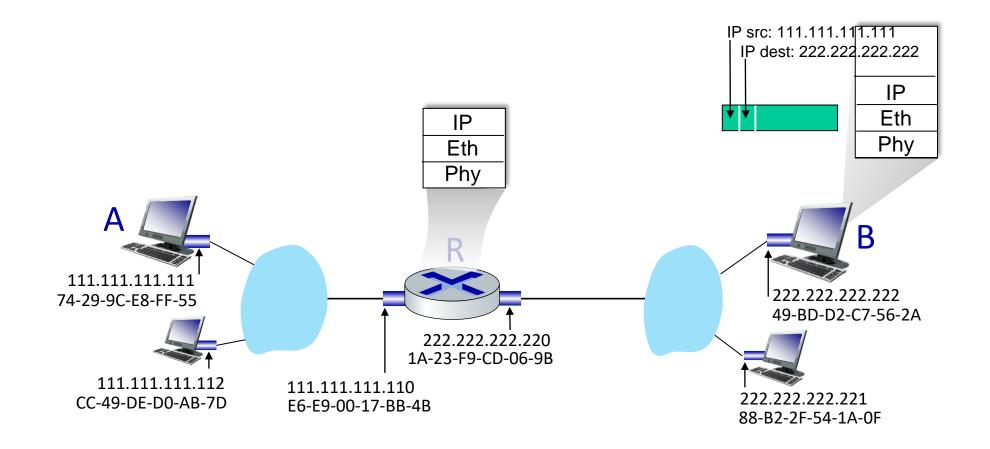

- R determines outgoing interface, passes datagram with IP source A, destination B to link layer
- R creates link-layer frame containing A-to-B IP datagram. Frame destination address: B's MAC address

- R determines outgoing interface, passes datagram with IP source A, destination B to link layer
- R creates link-layer frame containing A-to-B IP datagram. Frame destination address: B's MAC address

- B receives frame, extracts IP datagram destination B
- B passes datagram up protocol stack to IP

Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANs
- link virtualization: MPLS
- data center networking

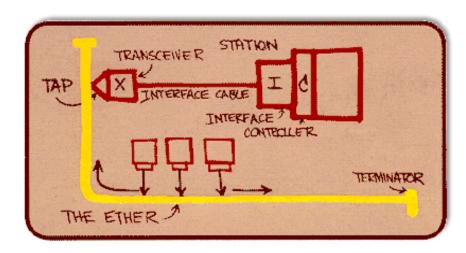

a day in the life of a web request

Ethernet

"dominant" wired LAN technology:

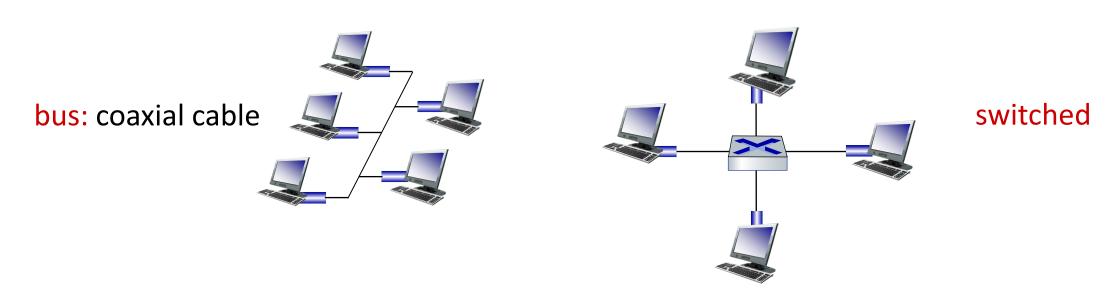

- first widely used LAN technology
- simpler, cheap
- kept up with speed race: 10 Mbps 400 Gbps
- single chip, multiple speeds (e.g., Broadcom BCM5761)

Metcalfe's Ethernet sketch

Ethernet: physical topology

- bus: popular through mid 90s
 - all nodes in same collision domain (can collide with each other)
- switched: prevails today
 - active link-layer 2 switch in center
 - each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

Ethernet frame structure

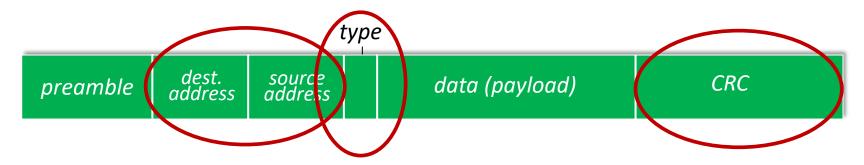

sending interface encapsulates IP datagram (or other network layer protocol packet) in Ethernet frame

preamble:

- used to synchronize receiver, sender clock rates
- 7 bytes of 10101010 followed by one byte of 10101011

Ethernet frame structure (more)

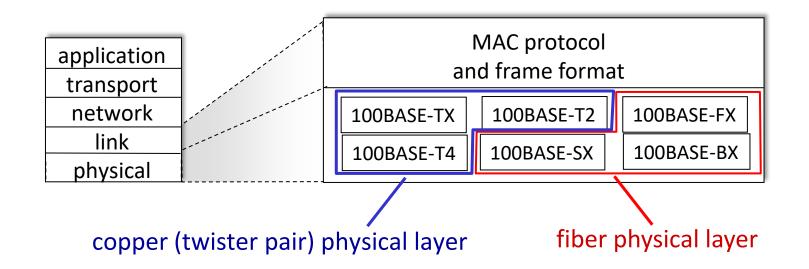

- addresses: 6 byte source, destination MAC addresses
 - if adapter receives frame with matching destination address, or with broadcast address (e.g., ARP packet), it passes data in frame to network layer protocol
 - otherwise, adapter discards frame
- type: indicates higher layer protocol
 - mostly IP but others possible, e.g., Novell IPX, AppleTalk
 - used to demultiplex up at receiver
- CRC: cyclic redundancy check at receiver
 - error detected: frame is dropped

Ethernet: unreliable, connectionless

- connectionless: no handshaking between sending and receiving NICs
- •unreliable: receiving NIC doesn't send ACKs or NAKs to sending NIC
 - data in dropped frames recovered only if initial sender uses higher layer rdt (e.g., TCP), otherwise dropped data lost
- Ethernet's MAC protocol: unslotted CSMA/CD with binary backoff

802.3 Ethernet standards: link & physical layers

- many different Ethernet standards
 - common MAC protocol and frame format
 - different speeds: 2 Mbps, 10 Mbps, 100 Mbps, 1Gbps, 10 Gbps, 40 Gbps
 - different physical layer media: fiber, cable

Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANs
- link virtualization: MPLS
- data center networking

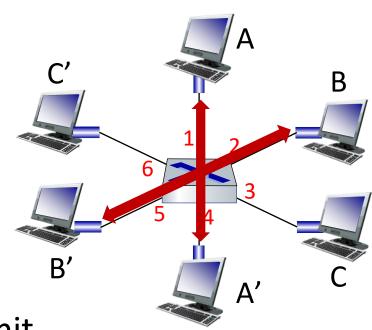

a day in the life of a web request

Ethernet switch

- Switch is a link-layer device: takes an active role
 - store, forward Ethernet frames
 - examine incoming frame's MAC address, selectively forward frame to one-or-more outgoing links when frame is to be forwarded on segment
- transparent: hosts unaware of presence of switches
- plug-and-play, self-learning
 - switches do not need to be configured

Switch: multiple simultaneous transmissions

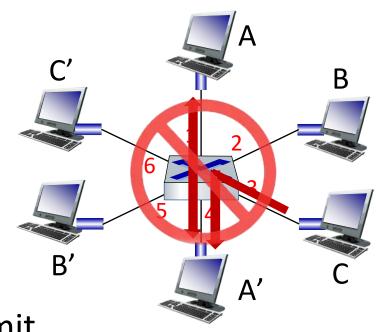

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, so:
 - no collisions; full duplex
 - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions

switch with six interfaces (1,2,3,4,5,6)

Switch: multiple simultaneous transmissions

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, so:
 - no collisions; full duplex
 - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions
 - but A-to-A' and C to A' can not happen simultaneously

switch with six interfaces (1,2,3,4,5,6)

Switch forwarding table

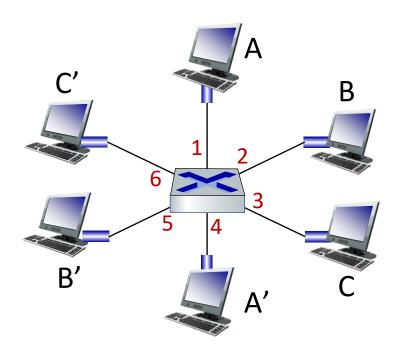

Q: how does switch know A' reachable via interface 4, B' reachable via interface 5?

<u>A:</u> each switch has a switch table, each entry:

- (MAC address of host, interface to reach host, time stamp)
- looks like a routing table!

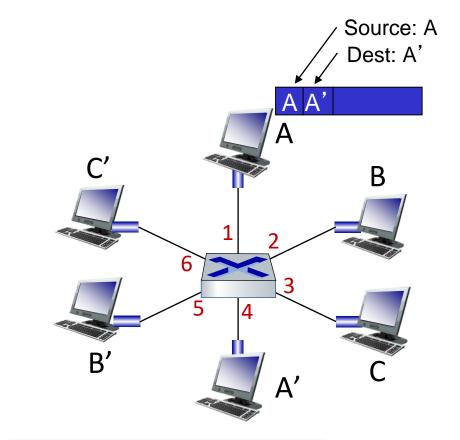

Q: how are entries created, maintained in switch table?

something like a routing protocol?

Switch: self-learning

- switch *learns* which hosts can be reached through which interfaces
 - when frame received, switch "learns" location of sender: incoming LAN segment
 - records sender/location pair in switch table

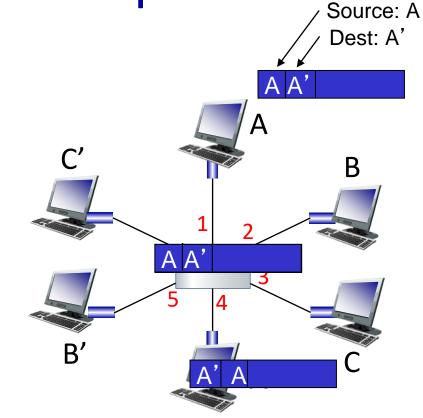

MAC addr	interface	TTL
Α	1	60

Switch table (initially empty)

Self-learning, forwarding: example

- frame destination, A', location unknown: flood
- destination A location known: selectively send

on just one link

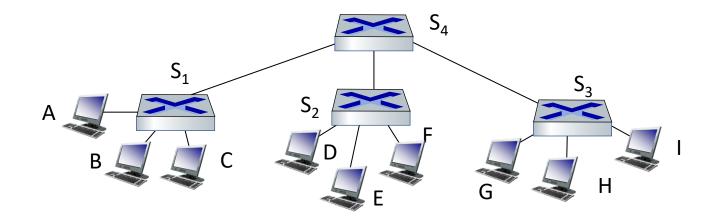

MAC addr	interface	TTL
Α Δ'	1 1	60 60
	7	

switch table (initially empty)

Interconnecting switches

self-learning switches can be connected together:

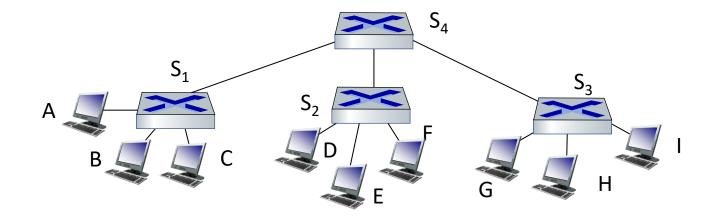

Q: sending from A to G - how does S_1 know to forward frame destined to G via S_4 and S_3 ?

• A: self learning! (works exactly the same as in single-switch case!)

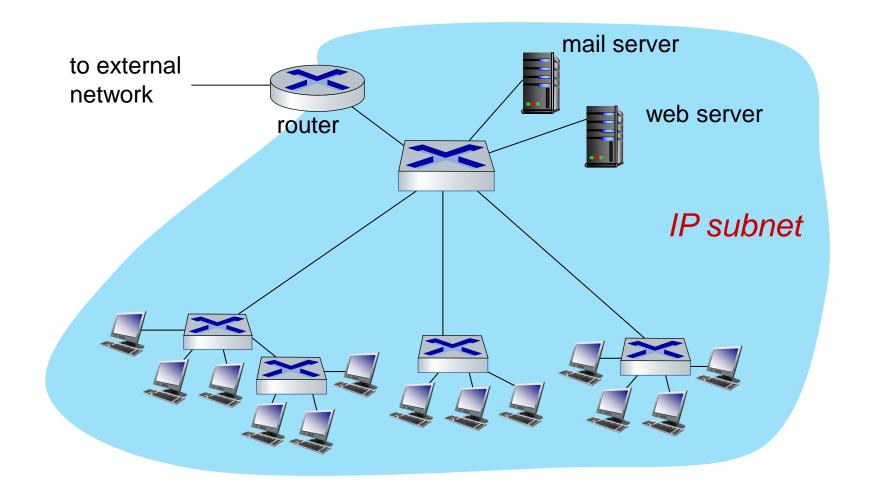

Self-learning multi-switch example

Suppose A sends frame to H, H responds to A

 \underline{Q} : show switch tables and packet forwarding in S_1 , S_2 , S_3 , S_4

Small institutional network

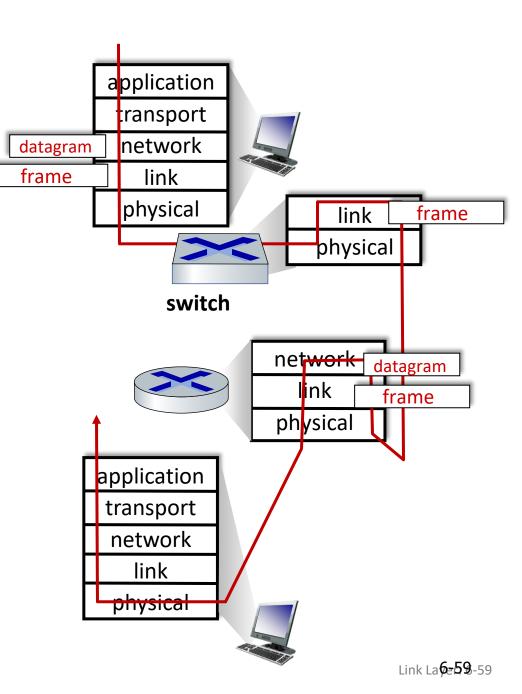

Switches vs. routers

both are store-and-forward:

- routers: network-layer devices (examine network-layer headers)
- switches: link-layer devices (examine link-layer headers)

both have forwarding tables:

- routers: compute tables using routing algorithms, IP addresses
- switches: learn forwarding table using flooding, learning, MAC addresses

Link layer, LANs: roadmap

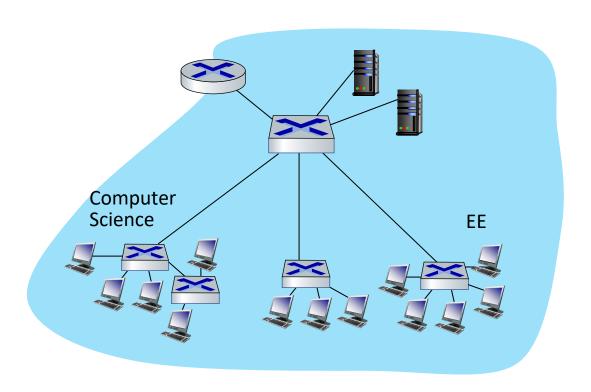

- introduction
- error detection, correction
- multiple access protocols
- LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANs
- data center networking

a day in the life of a web request

Virtual LANs (VLANs): motivation

Q: what happens as LAN sizes scale, users change point of attachment?

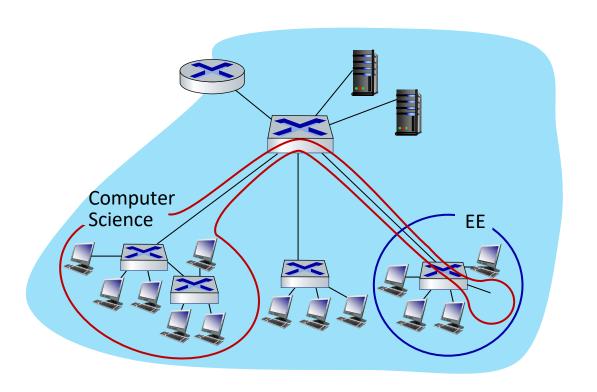

single broadcast domain:

- scaling: all layer-2 broadcast traffic (ARP, DHCP, unknown MAC) must cross entire LAN
- efficiency, security, privacy issues

Virtual LANs (VLANs): motivation

Q: what happens as LAN sizes scale, users change point of attachment?

single broadcast domain:

- scaling: all layer-2 broadcast traffic (ARP, DHCP, unknown MAC) must cross entire LAN
- efficiency, security, privacy, efficiency issues

administrative issues:

 CS user moves office to EE - physically attached to EE switch, but wants to remain logically attached to CS switch

Port-based VLANs

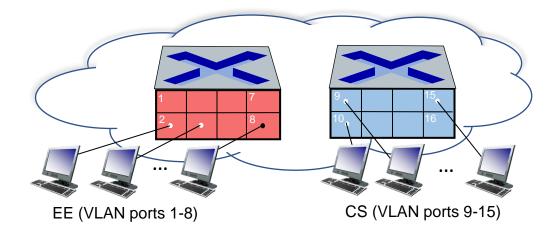

Virtual Local Area Network (VLAN)

switch(es) supporting VLAN capabilities can be configured to define multiple *virtual* LANS over single physical LAN infrastructure.

port-based VLAN: switch ports grouped (by switch management software) so that single physical switch

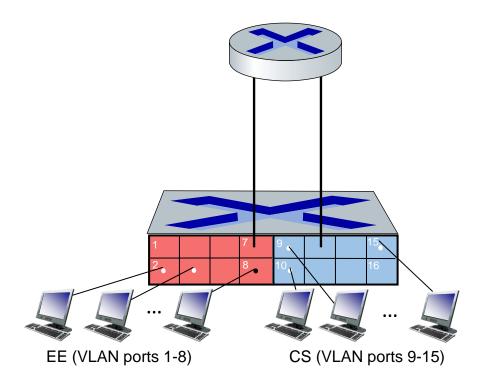

... operates as multiple virtual switches

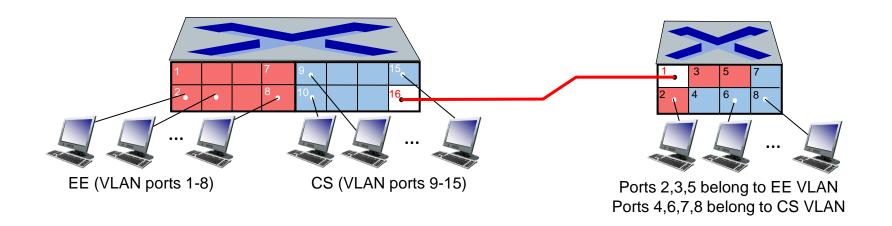

Port-based VLANs

- traffic isolation: frames to/from ports1-8 can only reach ports 1-8
 - can also define VLAN based on MAC addresses of endpoints, rather than switch port
- dynamic membership: ports can be dynamically assigned among VLANs
- forwarding between VLANS: done via routing (just as with separate switches)
 - in practice vendors sell combined switches plus routers

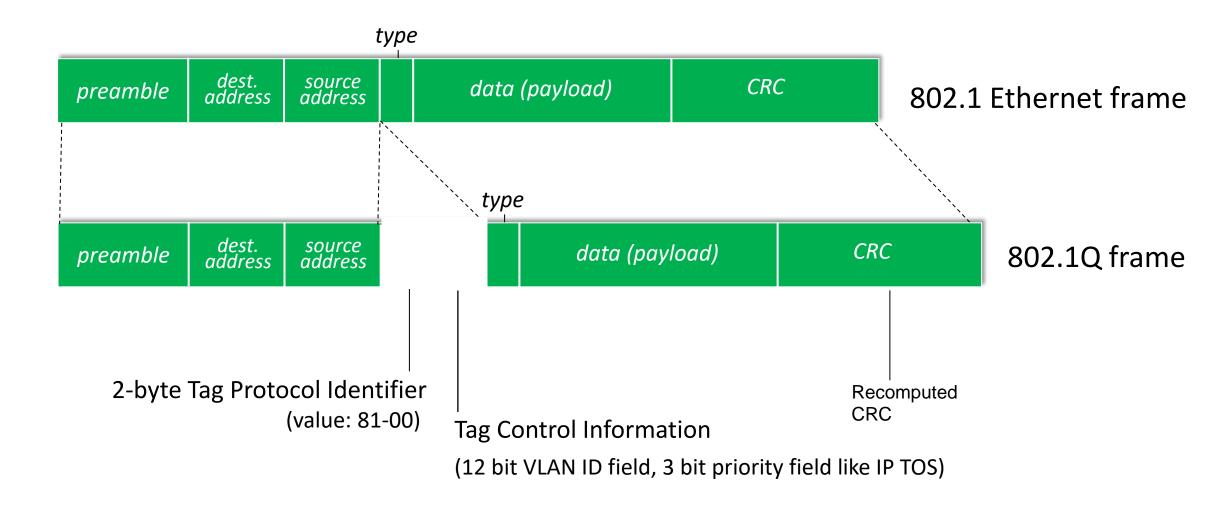

VLANS spanning multiple switches

trunk port: carries frames between VLANS defined over multiple physical switches

- frames forwarded within VLAN between switches can't be vanilla 802.1 frames (must carry VLAN ID info)
- 802.1q protocol adds/removed additional header fields for frames forwarded between trunk ports

802.1Q VLAN frame format

Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANs
- link virtualization: MPLS
- data center networking

a day in the life of a web request

Datacenter networks

10's to 100's of thousands of hosts, often closely coupled, in close proximity:

- e-business (e.g. Amazon)
- content-servers (e.g., YouTube, Akamai, Apple, Microsoft)
- search engines, data mining (e.g., Google)

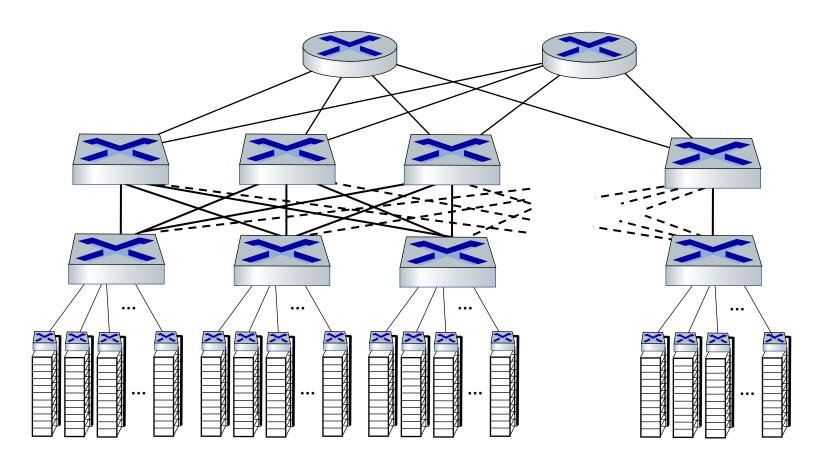

challenges:

- multiple applications, each serving massive numbers of clients
- reliability
- managing/balancing load, avoiding processing, networking, data bottlenecks

Inside a 40-ft Microsoft container, Chicago data center

Datacenter networks: network elements (fat-tree)

Border routers

connections outside datacenter

Tier-1 switches

connecting to ~16 T-2s below

Tier-2 switches

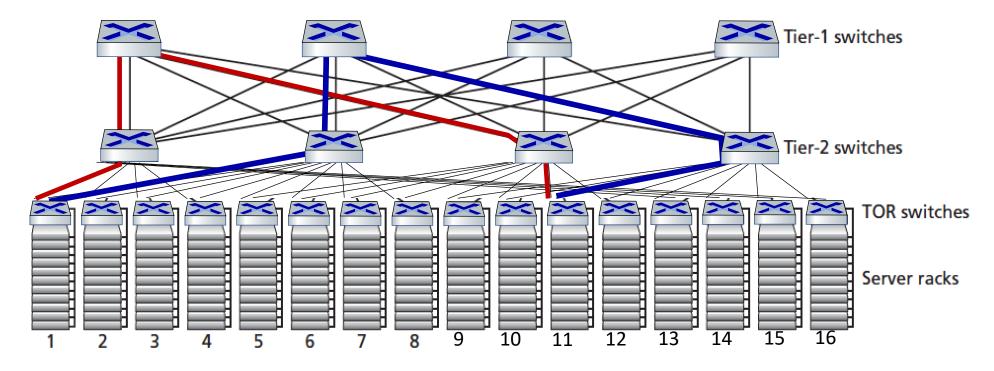

connecting to ~16 TORs below

Top of Rack (TOR) switch

- one per rack
- 40-100Gbps Ethernet to blades

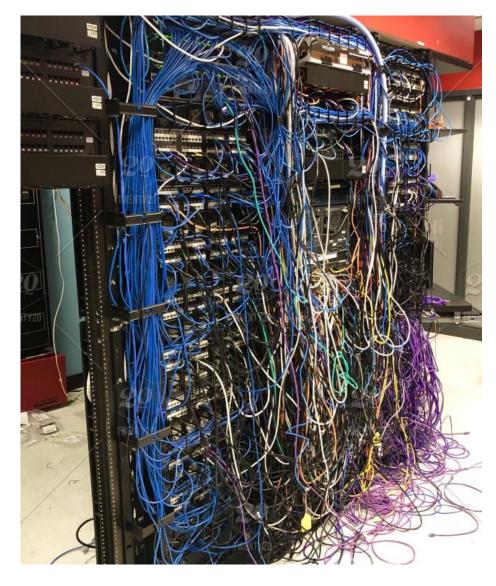

Datacenter networks: multipath (fat-tree)

- rich interconnection among switches, racks:
 - increased throughput between racks (multiple routing paths possible)
 - increased reliability via redundancy

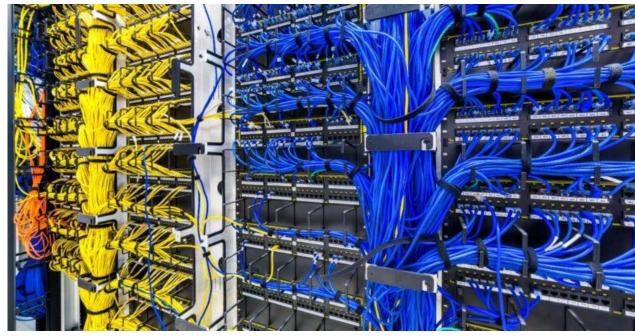

two disjoint paths highlighted between racks 1 and 11

Datacenter networks: multipath (fat-tree)

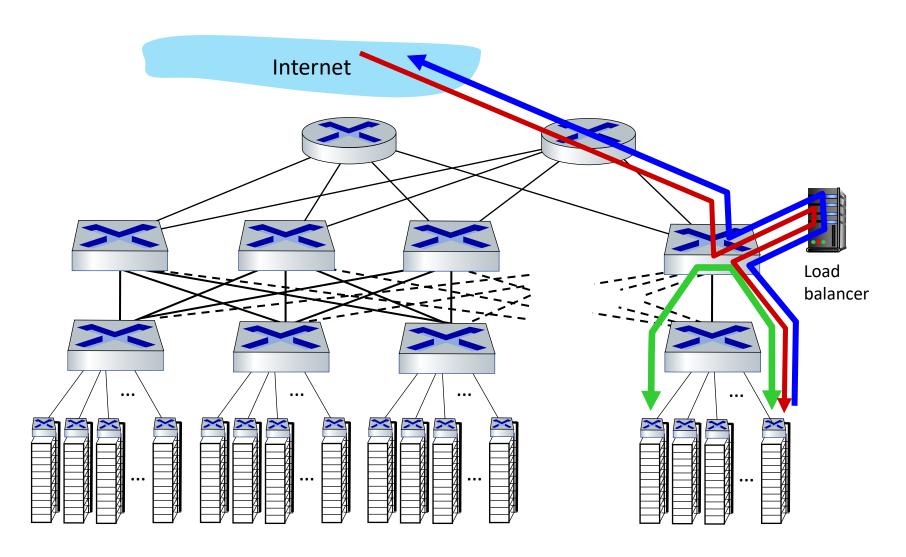

Datacenter networks: multipath (fat-tree)

Datacenter networks: application-layer routing

load balancer: application-layer routing

- receives external client requests
- directs workload within data center
- returns results to external client (hiding data center internals from client)

Datacenter networks: protocol innovations

link layer:

• RoCE: remote DMA (RDMA) over Converged Ethernet

transport layer:

- ECN (explicit congestion notification) used in transport-layer congestion control (DCTCP, DCQCN)
- experimentation with hop-by-hop (backpressure) congestion control

routing, management:

- SDN widely used within/among organizations' datacenters
- place related services, data as close as possible (e.g., in same rack or nearby rack) to minimize tier-2, tier-1 communication

Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
 - addressing, ARP
 - Ethernet
 - switches
 - VLANs
- link virtualization: MPLS
- data center networking

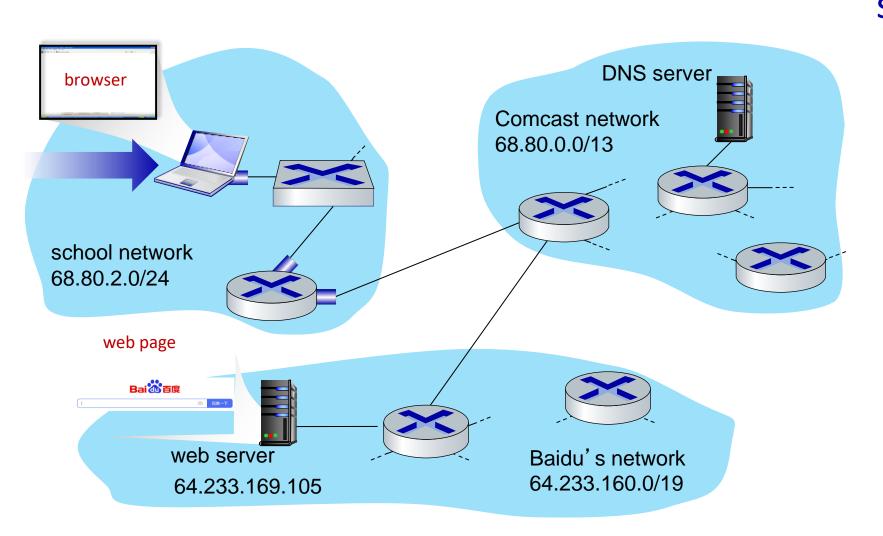

a day in the life of a web request

Synthesis: a day in the life of a web request

- our journey down the protocol stack is now complete!
 - application, transport, network, link
- putting-it-all-together: synthesis!
 - *goal*: identify, review, understand protocols (at all layers) involved in seemingly simple scenario: requesting www page
 - *scenario:* student attaches laptop to campus network, requests/receives www.baidu.com

A day in the life: scenario

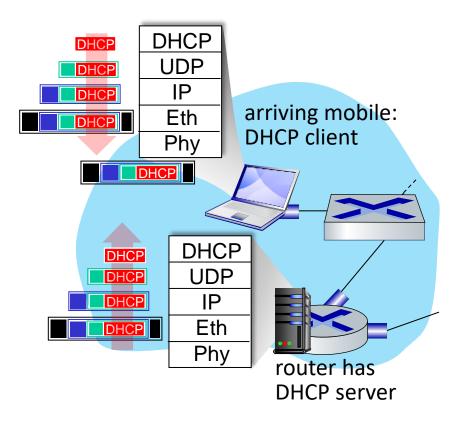

scenario:

- arriving mobile client attaches to network ...
- requests web page: www.baidu.com

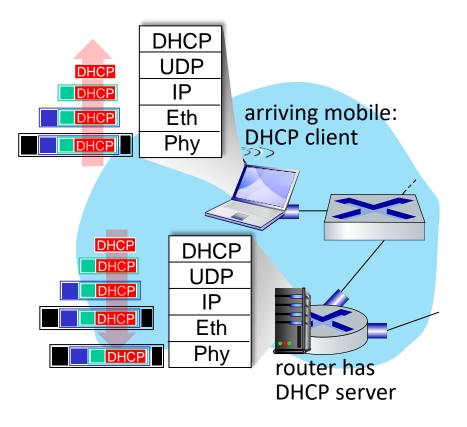

A day in the life: connecting to the Internet

- connecting laptop needs to get its own IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802.3 Ethernet
- Ethernet demuxed to IP demuxed, UDP demuxed to DHCP

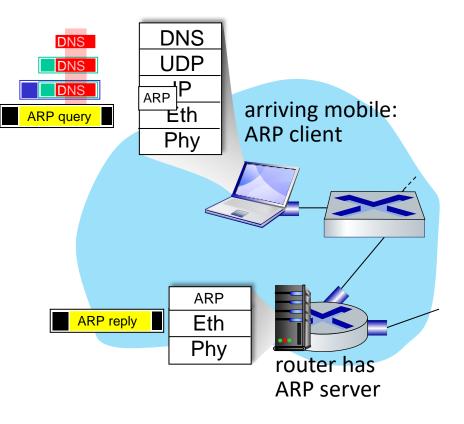

A day in the life: connecting to the Internet

- DHCP server formulates DHCP ACK containing client's IP address, IP address of first-hop router for client, name & IP address of DNS server
- encapsulation at DHCP server, frame forwarded (switch learning) through LAN, demultiplexing at client
- DHCP client receives DHCP ACK reply

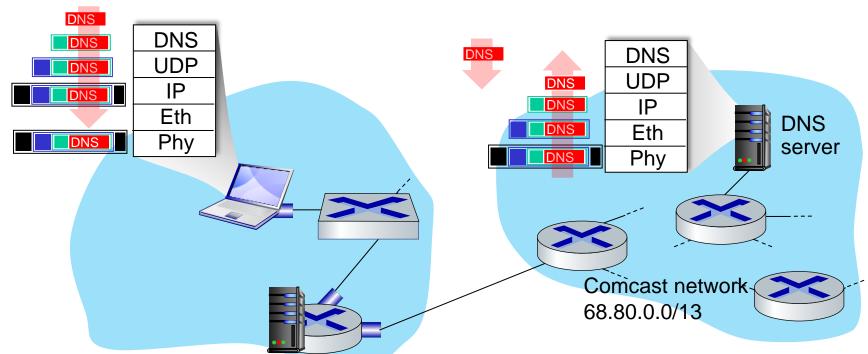

Client now has IP address, knows name & addr of DNS server, IP address of its first-hop router

A day in the life... ARP (before DNS, before HTTP)

- before sending HTTP request, need IP address of www.baidu.com: DNS
- DNS query created, encapsulated in UDP, encapsulated in IP, encapsulated in Eth. To send frame to router, need MAC address of router interface: ARP
- ARP query broadcast, received by router, which replies with ARP reply giving MAC address of router interface
- client now knows MAC address of first hop router, so can now send frame containing DNS query

A day in the life... using DNS

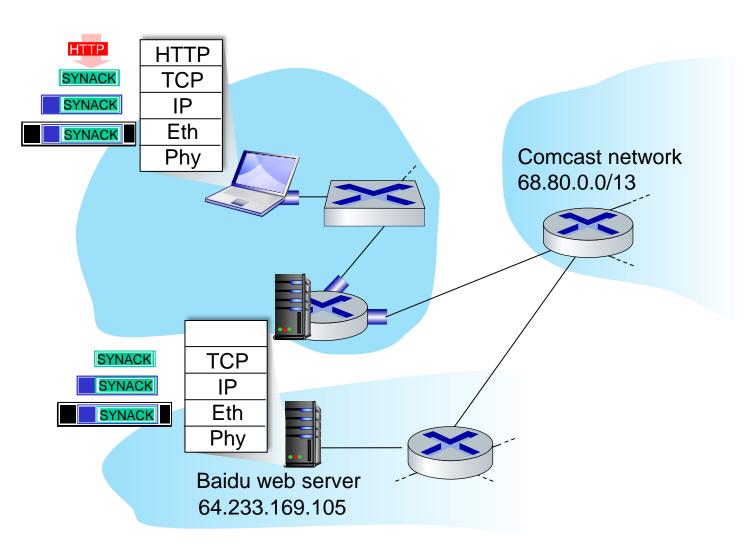

- demuxed to DNS
- DNS replies to client with IP address of www.baidu.com

 IP datagram containing DNS query forwarded via LAN switch from client to 1st hop router

 IP datagram forwarded from campus network into Comcast network, routed (tables created by RIP, OSPF, IS-IS and/or BGP routing protocols) to DNS server

A day in the life...TCP connection carrying HTTP

- to send HTTP request, client first opens TCP socket to web server
- TCP SYN segment (step 1 in TCP 3-way handshake) interdomain routed to web server
- web server responds with TCP SYNACK (step 2 in TCP 3way handshake)
- TCP connection established!

A day in the life... HTTP request/reply

- HTTP request sent into
 TCP socket
- IP datagram containing HTTP request routed to www.baidu.com
- web server responds with HTTP reply (containing web page)
- IP datagram containing HTTP reply routed back to client

Chapter 6: Summary

- principles behind data link layer services:
 - error detection, correction
 - sharing a broadcast channel: multiple access
 - link layer addressing
- instantiation, implementation of various link layer technologies
 - Ethernet
 - switched LANS, VLANs
 - virtualized networks as a link layer: MPLS
- synthesis: a day in the life of a web request
